

Architecture Verification Problems Report

1. Verification Overview

This report documents verification failures detected in the architecture description. Validation was not performed because the ADL is not fully verified.

Verification Scope

Verification evaluates the architectural description independently of quality attributes. It focuses on structural correctness, architectural completeness, and internal consistency.

2. Verification Result

Verification Status: **NOT VERIFIED**

Failed Layer: **Consistency**

3. Consistency Verification Analysis

Consistency verification ensures that architectural elements, metrics, and declared styles do not contradict each other. The following issues indicate internal architectural inconsistencies.

Rule	Description
STYLE_COMMUNICATION_CONFLICT	Microservices architecture uses synchronous communication.
STYLE_STATE_CONFLICT	High state concentration conflicts with microservices style.

4. Verification Conclusion

Due to the verification failures reported above, the architecture description cannot be considered reliable for validation. The detected issues must be resolved before quality and domain-level validation can be meaningfully performed.
